Abstract

Starting from the general expression for the ground state correlation energy in the adiabatic connection fluctuation dissipation theorem (ACFDT) framework, it is shown that the dielectric matrix formulation, which is usually applied to calculate the direct random phase approximation (dRPA) correlation energy, can be used for alternative RPA expressions including exchange effects. Within this framework, the ACFDT analog of the second order screened exchange (SOSEX) approximation leads to a logarithmic formula for the correlation energy.

similar to the direct RPA expression. Alternatively, the contribution of the exchange can be included in the kernel used to evaluate the response functions. In this case the use of an approximate kernel is crucial to simplify the formalism and to obtain a correlation energy in logarithmic form. Technical details of the implementation of these methods are discussed and it is shown that one can take advantage of density fitting or Cholesky decomposition techniques to improve the computational efficiency; a discussion on the numerical quadrature made on the frequency variable is also provided. A series of test calculations on atomic correlation energies and molecular reaction energies shows that exchange effects are instrumental to improve over direct RPA results.

1 Introduction

In the past few years, random phase approximation (RPA) approaches, which belong to the methods on the 5th rung of Jacob’s ladder,\(^1\) have been on the way of becoming a practical tool to construct correlation energy functionals.\(^2\)\textsuperscript{–23} Specifically, within the framework of the adiabatic-connection fluctuation-dissipation-theorem (ACFDT), the electronic correlation energy is expressed in terms of dynamical (frequency-dependent) linear response functions and the electron-electron interaction is gradually switched on from the independent particle reference to the fully interacting state using an adiabatic connection parameter. Therefore the correlation energy takes the form of a multiple integral involving both the frequency and the adiabatic connection parameters. Instead of the exact linear response function, convenient approximations, like the RPA, are used.

Among the numerous possible ways to express the RPA ground state correlation energy, depending on the order in which the analytical and/or numerical frequency- and interaction strength-integrations are performed, one may cite (1) the density matrix formulation,\(^2\) which leads to expressions involving numerical integration over the interaction strength and (2) the dielectric matrix formulation which involves a numerical integral over frequency of a logarithmic expression involving the dynamical dielectric function. This approach has mainly been used by solid state theorists\(^4,9,12,24\) and recently adapted also in a density fitting framework by Furche \textit{et al.}\(^25\) Within
this formulation the direct calculation of the lowest eigenvalues and eigenvectors of the dielectric matrix can be used to achieve a more compact representation of dielectric functions. Finally, there are approaches which avoid numerical integration altogether, like (3) the plasmon formula, obtained after a double analytical integration on both the frequency and the interaction strength. An elegant way to obtain the plasmon expression consists in solving the algebraic Riccati-equations of the RPA problem. This method has been shown to be strictly equivalent to a coupled cluster doubles approach in the ring-approximation (rCCD). Modifications and approximations to the rCCD equations and energy expression has led to a whole class of additional RPA-based approaches for the ground state correlation energy.

The RPA problem can be set up either with the inclusion of nonlocal exchange effects (leading to a class of approximations denoted RPAx) or by restricting the coupling between independent particle responses to the direct Hartree interaction (leading to the class denoted dRPA). Additionally, according to the classification and nomenclature proposed in Ref. 33, RPA methods for the ground-state correlation energy can be sought in two main flavors: either by the complete neglect of the exchange integrals, i.e. by taking the contraction of the dRPA response function with non-antisymmetrized two-electron integrals (dRPA-I), or by a full consideration of non-local exchange, when antisymmetrized two-electron integrals are contracted with the RPAX response function matrix elements (RPAX-II). This latter approach has been followed by some early works in quantum chemistry, based on Hartree-Fock orbitals, while dRPA is usually the method of choice in the density functional context, starting from Kohn-Sham orbitals. Partial inclusion/omission of nonlocal exchange leads to "mixed" methodologies, like dRPA-II and RPAX-I.

Recently, it has been suggested that certain shortcomings of the dRPA correlation energy can be remedied by including nonlocal exchange interactions in a perturbative way, i.e. with the dRPA polarization propagator being contracted with a list of fully antisymmetrized two-electron integrals. We can mention, in this aspect, the SOSEX (second order screened exchange) corrections, which have been formulated originally within the rCCD formalism. It has been pointed out that "it is difficult to motivate this approximation in the framework of ACFDT".
seems to be somewhat paradoxical, since the plasmon formula, identical to the rCCD correlation energy expression, can be derived from ACFDT in a straightforward manner, and there is no fundamental reason to think that an analogous derivation is impossible for SOSEX. In fact, it has been shown recently that a very similar perturbative screened exchange formula, which has been designated by the acronym dRPA-IIa, can be obtained within the density matrix formulation of RPA. Although this expression gives correlation energies numerically very close to the rCCD-based SOSEX, it has been proven that they are not strictly identical.

In this work we discuss different approximations to efficiently include exchange effects within the dielectric matrix formulation of the RPA correlation energy. In a quantum chemical context these methodologies provide an alternative to the ring-CCD-based RPA formalism. Additionally, these methods are of significant interest for the solid state physics community, where the dielectric matrix approach is almost exclusively used. As it will be shown in the following, the dRPA-IIa approximation can be derived also in the dielectric matrix formulation of RPA, leading to an alternative algorithm to calculate the SOSEX-like dRPA-IIa energy. At the same time we have access to the conventional MP2 energy, which corresponds to the lowest non-vanishing term in the series expansion of the dRPA-IIa correlation energy. We note that approximations in the RPAx class lead to other correlation energy estimates, which can be also adapted to the logarithmic formulation. Specifically, the RPAx-Ia approximation is derived, which includes only the particle-hole contribution to the exchange kernel. It will be shown that this last approach provides the most promising results in the numerical tests considered in this work.

In Sec. 2.1, the working equations for the well-known dielectric matrix formulation of the direct RPA method will be derived from the ACFDT. This version is particularly simple because of the complete neglect of the exchange effects. Incorporation of exchange leads to a more complicated expression and one is constrained to apply various additional approximations to obtain practical expressions. As discussed in Sec. 2.2, one possibility is a SOSEX-like correlation energy expression, which is the dielectric matrix formulation of the dRPA-IIa variant. In Sec. 2.3 we will discuss an additional variant, which includes exchange effects in the response function. The
possible practical implementations of these methodologies are discussed in some details in Sec. 3. Several atomic and molecular systems will be used for numerical illustration of the formalism, in Sec. 4. Finally, Sec. 5 contains our conclusions.

2 RPA versions from ACFDT and their dielectric matrix formulation

In the adiabatic-connection fluctuation-dissipation theorem (ACFDT) approach the correlation energy reads as: \(^38,39\)

\[
E_{\text{ACFDT}}^c = -\frac{1}{2} \int_0^1 d\alpha \int_{-\infty}^{\infty} \frac{d\omega}{2\pi} \text{Tr} \{ \Pi_\alpha(i\omega) \mathcal{G} - \Pi_0(i\omega) \mathcal{G} \},
\]

(1)

where \(\mathcal{G}\) is the matrix representation of the interaction which contains two-electron integrals (see Eqs. (7) and (16)). In Eq. 1 the four-index matrix representation of the dynamical polarization propagator \(\Pi_\alpha(i\omega)\) (also called density matrix response function) at interaction strength \(\alpha\) is obtained from a Dyson-like equation,

\[
\Pi_\alpha(i\omega) = (1 - \alpha \Pi_0(i\omega) \mathcal{F})^{-1} \Pi_0(i\omega),
\]

(2)

where \(\mathcal{F}\) is the interaction kernel matrix (see Eqs. (7) and (24)). In the two previous equations, the polarization propagator of the non-interacting reference system, \(\Pi_0(i\omega)\), is given by:

\[
\Pi_0(i\omega) = -(\mathbf{\Lambda}_0 - i\omega \Delta)^{-1},
\]

(3)

with
\[ \Lambda_0 = \begin{pmatrix} \epsilon & 0 \\ 0 & \epsilon \end{pmatrix} \quad \text{and} \quad \Delta = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}. \] (4)

In the random phase approximation (RPA), the elements of the \( \Lambda_0 \) matrix are the independent one-particle excitation energies: \((\epsilon_{ia, jb} = \epsilon_{ia} \delta_{ij} \delta_{ab})\), where \( \epsilon_{ia} = \epsilon_a - \epsilon_i \), \( \epsilon_a \) is the energy of a virtual orbital and \( \epsilon_i \) the energy of an occupied orbital. Here and in the following we assume that a finite-dimensional basis set is used for the representation of occupied and virtual orbitals.

The polarization propagator of the non-interacting reference system then reads:

\[ \Pi_0(i\omega) = \begin{pmatrix} \Pi_0^+(i\omega) & 0 \\ 0 & \Pi_0^-(i\omega) \end{pmatrix}, \] (5)

which introduces compact notations for the diagonal blocks, \( \Pi_0^+(i\omega) = -(\epsilon - i\omega 1)^{-1} \) and \( \Pi_0^-(i\omega) = -(\epsilon + i\omega 1)^{-1} \).

The dimensions of the matrices appearing in Eq. (1) are \( (2N_{\text{exc}} \times 2N_{\text{exc}}) \), where \( N_{\text{exc}} \) is the number of the products between occupied and virtual orbitals. However, since we need only the trace for the correlation energy, the same result can be obtained using matrices with a dimension reduced to \( (N_{\text{exc}} \times N_{\text{exc}}) \), as it will be shown below.

In several earlier works\(^{15,40}\) the derivation of the logarithmic energy expression have been based on a Taylor expansion of matrix functions (namely the inverse and the logarithmic functions). Such a procedure raises some problems of general validity, since the conditions for an absolute convergence of the series expansions cannot be always satisfied. Below, we propose an alternative derivation using matrix functions, which requires only the weaker condition that the matrix be diagonalizable. The general definition of a matrix function is

\[ \text{\ldots} \]
\[ f(A) = Q f(D) Q^{-1}, \]  
\[ (6) \]

where \( A = QDQ^{-1} \) is the eigendecomposition of the matrix \( A \). Hence, all along the manuscript, the matrices \( D \) are diagonal matrices of eigenvalues and \( Q \) are eigenvectors.

### 2.1 Direct RPA

In the direct RPA (dRPA), the nonlocal Hartree-Fock exchange is not taken into account in the interaction kernel \( \mathcal{F} \) of the Dyson-like equation in Eq. (2). Furthermore, we will first consider an interaction matrix \( \mathcal{G} \) constituted of non-antisymmetrized two-electron integrals in Eq. (1). This yields:

\[ \mathcal{F} = \mathcal{G} = \mathcal{V} = \begin{pmatrix} K & K \\ K & K \end{pmatrix}, \]
\[ (7) \]

where \( K_{ia,jb} = \langle ij|ab \rangle \) are the non-antisymmetrized two-electron integrals (physicist’s notation) in spin-orbitals. In this situation, one only has to deal with the matrix product \( \Pi_0(i\omega)^{\mathcal{V}} \) (see Eqs. (1) and (2)). Considering the block-structure of \( \Pi_0\mathcal{V} \),

\[ \Pi_0\mathcal{V} = \begin{pmatrix} \Pi_0^*K & \Pi_0^*K \\ \Pi_0K & \Pi_0K \end{pmatrix}, \]
\[ (8) \]

application of the following unitary transformation:
to the integrand of Eq. (1) yields:

\[
\mathcal{U} = \frac{1}{\sqrt{2}} \begin{pmatrix} I & I \\ I & -I \end{pmatrix},
\]

(9)

to the integrand of Eq. (1) yields:

\[
\text{Tr}\{(1 - \alpha \Pi_0(i\omega)\mathbb{V})^{-1} \Pi_0 \mathbb{V} - \Pi_0 \mathbb{V}\} = \text{tr}\{(1 - \alpha \Pi_0(i\omega)\mathbb{K})^{-1} \Pi_0 \mathbb{K} - \Pi_0 \mathbb{K}\},
\]

(10)

where we use the notation \(\Pi_0(i\omega) = \Pi_0^+(i\omega) + \Pi_0^-(i\omega)\). The notation \(\text{tr}\{X\}\) emphasizes that we have reduced the matrix dimensions as compared to \(\text{Tr}\{X\}\) (the same applies later to \(\det(X)/\text{Det}(X)\) and to \(\log(X)/\text{Log}(X)\)). Defining the function \(\Pi_\alpha(i\omega)\) that satisfies the \((N_{\text{exc}} \times N_{\text{exc}})\) dimension-reduced Dyson-like equation,

\[
\Pi_\alpha(i\omega) = (1 - \alpha \Pi_0(i\omega)\mathbb{K})^{-1} \Pi_0(i\omega),
\]

(11)

we retrieve the analog of Eq. (1) with dimension-reduced matrices

\[
E_{\text{c dRPA-1}} = -\frac{1}{2} \int_0^1 d\alpha \int_{-\infty}^{\infty} d\omega \frac{1}{2\pi} \text{tr}\{\Pi_\alpha(i\omega)\mathbb{K} - \Pi_0(i\omega)\mathbb{K}\}.
\]

(12)

Equation (12) can be further transformed either by an analytical frequency-integration, which leads to the density matrix expression of the dRPA correlation energy (this has already been discussed in a previous publication,\(^3^3\) and is briefly recalled in Appendix A), or by an analytical integration over the adiabatic connection parameter. This will be done by considering the eigenvalue decomposition of \(\Pi_0(i\omega)\mathbb{K}\). Using the dimension-reduced Dyson-like equation (Eq. 11), we express \(\Pi_\alpha(i\omega)\mathbb{K}\)
seen in Eq. (12) as a matrix function of $\Pi_0(i\omega)K$:

$$\Pi_{\alpha}(i\omega)K = Q(i\omega)(I - aD(i\omega))^{-1}D(i\omega)Q^{-1}(i\omega),$$  \hspace{1cm} (13)

where, as stated before, $D(i\omega)$ is the diagonal matrix of the eigenvalues of $\Pi_0(i\omega)K$ and $Q(i\omega)$ contains its eigenvectors. Using the cyclic invariance of the trace and denoting by $d_{ia}$ the $ia$-th diagonal element of $D$, Eq. (12) becomes

$$E_{c}^{dRPA-I} = -\frac{1}{2} \int_{-\infty}^{\infty} \frac{d\omega}{2\pi} \sum_{ia=1}^{N_{\text{exc}}} \int_{0}^{1} da \left\{ \frac{d_{ia}(i\omega)}{1 - ad_{ia}(i\omega)} - d_{ia}(i\omega) \right\}$$

$$= \frac{1}{2} \int_{-\infty}^{\infty} \frac{d\omega}{2\pi} \sum_{ia=1}^{N_{\text{exc}}} \{ \log(1 - d_{ia}(i\omega)) + d_{ia}(i\omega) \}$$

$$= \frac{1}{2} \int_{-\infty}^{\infty} \frac{d\omega}{2\pi} \text{tr} \{ \log (I - \Pi_0(i\omega)K) + \Pi_0(i\omega)K \}. \hspace{1cm} (14)$$

We recognize here the matrix representation of the dielectric function, $\epsilon(i\omega) = I - \Pi_0(i\omega)K$, and this expression may be called the dielectric matrix formulation of the dRPA-I correlation energy.

Although it might not be obvious at first sight, a further analytical integration on the frequency leads directly to the plasmon formula. Such a relationship has already been mentioned by McLachlan et al. in the sixties. Inversely, the dielectric matrix formulation can be derived from the plasmon formula, as it has been shown recently by Eshuis et al. In Appendix B, we present an alternative derivation of the plasmon formula for the dRPA-I correlation energy from the dielectric formulation of Eq. (12). This seals the strict equivalence of all formalisms in the case of dRPA-I. Notice that the plasmon formula applies only to the dRPA-I (and to the RPAlx-II, which is not discussed here) energy expressions.

Moreover, doing a series expansion of the matrix logarithm in Eq. (14) and retaining only the first non-vanishing term, we obtain:
\[
E^{dRPA-II}_c = -\frac{1}{4} \int_{-\infty}^{\infty} \frac{d\omega}{2\pi} \text{Tr} \left\{ \Pi_0(i\omega) K \Pi_0(i\omega) K \right\} \\
= \frac{1}{4} \int_{-\infty}^{\infty} \frac{d\omega}{2\pi} \sum_{ia,jb} \left\{ \frac{-2\epsilon_{ia}}{\epsilon_{ia}^2 + \omega^2} K_{ia,jb} - \frac{-2\epsilon_{jb}}{\epsilon_{jb}^2 + \omega^2} K_{jb,ia} \right\} \\
= \frac{1}{2} \sum_{ia,jb} K_{ia,jb} K_{jb,ia} = E^{dMP2}_c,
\]
which corresponds to a direct-MP2 method, that is to say a version of the MP2 energy without exchange terms \(^2\) (in its range-separated variant, JMP2 \(^42\)).

### 2.2 RPA+SOSEX

Considering the fact that, in the ACFDT expression, the polarization propagator carries information about the screening properties in the system, a SOSEX-like Ansatz consists in replacing the direct interaction matrix \(V\) by the antisymmetrized expression \(\mathcal{W}\),

\[
\mathcal{G} = \mathcal{W} = \begin{pmatrix} A' & B \\ B & A \end{pmatrix},
\]

where the antisymmetrized two-electron integral matrices have the elements \(A'_{ia,jb} = \langle ib|a j \rangle - \langle ib|ja \rangle\) and \(B_{ia,jb} = \langle ij|ab \rangle - \langle ij|ba \rangle\). This particular form of the interaction matrix can be derived from the time dependent Hartree-Fock equations using the fact that the independent particle wave function, providing the bare, unscreened response, satisfies the Brillouin theorem. We note that one can argue for other choices of the \(\mathcal{W}\) matrix (vide infra).

The resulting correlation energy expression corresponds to the dRPA-II variant,

\[
E^{dRPA-II}_c = -\frac{1}{2} \int_{0}^{1} d\alpha \int_{-\infty}^{\infty} \frac{d\omega}{2\pi} \text{Tr} \left\{ \Pi_\alpha(i\omega) \mathcal{W} - \Pi_0(i\omega) \mathcal{W} \right\},
\]
which can be designated also as screened exchange dRPA (dRPA-SX), since the dRPA response function screens the full, Coulomb plus exchange interaction represented by the matrix $\mathbb{W}$.

As a consequence of the more complicated block structure of the $\mathbb{W}$ interaction matrix, it is less obvious to reduce the dimensions of the problem in the dRPA-II correlation energy as compared to the dRPA-I case. It is reasonable to decompose $\mathbb{W}$ into a "major" contribution, involving four identical blocks $\mathbb{B}$ and a "minor" correction, which consists in the $(A' - B)$ difference of the diagonal blocks:

$$
\mathbb{W} = \begin{pmatrix} \mathbb{B} & \mathbb{B} \\ \mathbb{B} & \mathbb{B} \end{pmatrix} + \begin{pmatrix} (A' - B) & 0 \\ 0 & (A' - B) \end{pmatrix}.
$$

The major contribution to the integrand can be brought to a convenient form by applying the unitary transformation $U$ (Eq. 9) to the matrix products under the trace in Eq. (17). After evaluating the inverse of the blocked matrix and subsequent matrix multiplications, one gets the trace of the major contribution in dimension-reduced matrices. The minor contribution to the energy expression of Eq. (17) can be neglected, as is shown in Appendix D, and this leads to the following approximation of the screened exchange dRPA, denoted in our previous publication as dRPA-IIa:

$$
E_{c \text{dRPA-IIa}} = -\frac{1}{2} \int_0^1 d\alpha \int_{-\infty}^{\infty} d\omega \frac{1}{2\pi} \text{tr} \{ \Pi_\alpha(i\omega) \mathbb{B} - \Pi_0(i\omega) \mathbb{B} \}.
$$

As in the dRPA-I case, after analytical frequency integration we get the same density matrix formulation expression as the one we have obtained in a quite different manner in Ref. 33. Before exploring another alternative, which consists in an analytical integration according to the interaction strength parameter, the reader must bear in mind the close analogy of dRPA-IIa and the so-called SOSEX (second order screened exchange) approximation, usually defined in the framework of a drCCD (direct ring coupled cluster doubles) theory. Although the above
ACFDT-based expression is not strictly equal to the drCCD-based SOSEX, their difference appears only at the third order of perturbation, as was demonstrated in Ref. 37. The difference of those two variants has been found numerically small for all of the systems studied up to now. The approximation, which leads from dRPA-II to dRPA-IIa shows in a self-explanatory manner the perturbation character of the SOSEX (dRPA-IIa), *i.e.* "second-order screened exchange" compared to the fully screened exchange (SX, *i.e.* dRPA-II) version.

In order to perform the analytical integration along the adiabatic connection path, we take advantage of the matrix function formalism (with now obvious notations for \( Q \) and \( d_{ia} \)):

\[
E_{c}^{dRPA-IIa} = -\frac{1}{2} \int_{-\infty}^{\infty} \frac{d\omega}{2\pi} \sum_{ia=1}^{N_{xc}} \int_{0}^{1} d\alpha \left\{ \left( (1 - \alpha d_{ia}(i\omega))^{-1} - 1 \right) \left( Q^{-1} \Pi_{0}(i\omega) BQ \right)_{ia,ia} \right\}
\]

\[
= \frac{1}{2} \int_{-\infty}^{\infty} \frac{d\omega}{2\pi} \sum_{ia=1}^{N_{xc}} \left\{ \left( \log(1 - d_{ia}(i\omega)) \right) d_{ia}^{-1}(i\omega) + 1 \right\} \left( Q^{-1} \Pi_{0}(i\omega) BQ \right)_{ia,ia}
\]

\[
= \frac{1}{2} \int_{-\infty}^{\infty} \frac{d\omega}{2\pi} \text{tr} \left\{ \log \left( I - \Pi_{0}(i\omega) K \right) K^{-1} B + \Pi_{0}(i\omega) B \right\}.
\]  

(20)

Particular care has to be taken to define the inverse of \( K \) in Eq. (20), since this matrix might be singular or close to singular in certain representations. Since the (close to) zero eigenvalues \( d_{ia}(i\omega) \) do not contribute to the sum over \( ia \) in Eq. (20), as can be seen from an expansion of the logarithm, it is implicit that \( K^{-1} = K^{-1} \Pi_{0}^{-1} \Pi_{0} = Q D^{-1} Q^{-1} \Pi_{0} \) is defined in terms of a pseudoinverse where \([D^{-1}]_{ia,ia} = d_{ia}^{-1}\) for finite \( d_{ia} \) and \([D^{-1}]_{ia,ia} = 0\) for \( d_{ia} = 0\) (or below a certain small threshold).

By decomposing the antisymmetrized two-electron integrals as \( B = K - \tilde{K} \), where the \( \tilde{K} \) matrix has the elements \( \tilde{K}_{ia,jb} = \langle ab|ji \rangle \), the correlation energy can be separated to a dRPA-I contribution and a SOSEX correction:

\[
E_{c}^{dRPA-IIa} = E_{c}^{dRPA-I} + E_{c}^{SOSEX}
\]

\[
E_{c}^{SOSEX} = -\frac{1}{2} \int_{-\infty}^{\infty} \frac{d\omega}{2\pi} \times \text{tr} \left\{ \left( \log \left( I - \Pi_{0}(i\omega) K \right) + \Pi_{0}(i\omega) K \right) K^{-1} \tilde{K} \right\}.
\]  

(21)

(22)
Furthermore, it is easy to verify that the second order approximation to the dRPA-IIa correlation energy is exactly the usual MP2 correlation energy (again by doing a series expansion of the matrix logarithm):

\[
E_{\text{dRPA-IIa}}^{(2)} = -\frac{1}{4} \int_{-\infty}^{\infty} \frac{d\omega}{2\pi} \text{tr} \{ \Pi_0(i\omega) K \Pi_0(i\omega) B \} = -\frac{1}{2} \sum_{ia,jb} K_{ia,jb} B_{jb,ia} \frac{\epsilon_{ia} + \epsilon_{jb}}{\epsilon_{ia} + \epsilon_{jb}} = E_{\text{c,MP2}}^{(23)}.
\]

An identical result has been obtained in the Appendix of Ref. 33. It is important to mention that in this context the MP2 correlation energy represents the first non-vanishing contribution to a converging series only if all the eigenvalues of \( \Pi_0(i\omega)K \) are smaller than 1.

### 2.3 Approximate RPA with exchange

The RPAX variants are based on a response function \( \Pi^{\text{RPAX}}_\alpha \) which fully takes into account the nonlocal exchange effects by a Hartree-Fock type kernel. In other words, the response function \( \Pi^{\text{RPAX}}_\alpha \) satisfies the following Dyson-like equation, where \( \mathcal{F} = \mathcal{W} \) in Eq. (2):

\[
\Pi^{\text{RPAX}}_\alpha(i\omega) = (I - \alpha \Pi_0(i\omega) \mathcal{W})^{-1} \Pi_0(i\omega).
\]

In the RPAX-I case, that is to say with \( \mathcal{G} = \mathcal{V} \) in Eq. (1), the ACFDT expression becomes:

\[
E_{\text{c,RPAX-I}} = -\frac{1}{2} \int_0^1 d\alpha \int_{-\infty}^{\infty} \frac{d\omega}{2\pi} \times \text{tr} \left\{ \left( I - \alpha \Pi_0(i\omega) \mathcal{W} \right)^{-1} \Pi_0(i\omega) \mathcal{V} - \Pi_0(i\omega) \mathcal{V} \right\}.
\]

Let us write again \( \mathcal{W} \) as a sum of two terms,
\[ \mathbb{W} = \begin{pmatrix} B & B \\ B & B \end{pmatrix} + \begin{pmatrix} A' - B & 0 \\ 0 & A' - B \end{pmatrix}, \quad (26) \]

and use the transformation \( \mathbb{U} \) on the matrix product under the trace. Neglecting the minor correction contribution leads to the RPAX-Ia energy:

\[ E_{c}^{\text{RPAX-Ia}} = -\frac{1}{2} \int_{0}^{1} d\alpha \int_{-\infty}^{\infty} \frac{d\omega}{2\pi} \text{tr} \left\{ \Pi_{\alpha}^{\text{RPAX}}(i\omega)K - \Pi_{0}(i\omega)K \right\}, \quad (27) \]

where we define \( \Pi_{\alpha}^{\text{RPAX}}(i\omega) \) which satisfies the dimension-reduced Dyson-like equation, obtained from Eq. (24) after taking an approximate kernel \( F^{\text{RPAX}} = \mathbb{B} \) including only the major contribution from Eq. (26):

\[ \Pi_{\alpha}^{\text{RPAX}}(i\omega) = (I - \alpha \Pi_{0}(i\omega)\mathbb{B})^{-1} \Pi_{0}(i\omega). \quad (28) \]

The notation RPAX (with capital X) refers to an analogy to an approximate RPA variant with exchange, proposed by Hesselmann.\(^{18}\) The relationships to Hesselmann’s approach will be discussed elsewhere. Comparison to Eqs. (19) and (11) shows that, formally, the roles of the matrices \( K \) and \( \mathbb{B} \) is merely exchanged with respect to the dRPA-IIa energy expression. Hence, the corresponding logarithmic formula obtained after \( \alpha \)-integration is:

\[ E_{c}^{\text{RPAX-Ia}} = \frac{1}{2} \int_{-\infty}^{\infty} \frac{d\omega}{2\pi} \text{tr} \left\{ \log(I - \Pi_{0}(i\omega)\mathbb{B}) \mathbb{B}^{-1}K + \Pi_{0}(i\omega)K \right\}. \quad (29) \]

again defining \( \mathbb{B}^{-1} \) in terms of a pseudoinverse involving the eigenvalues of \( \Pi_{0}(i\omega)\mathbb{B} \).

The second order approximation yields the MP2 energy in the exact same manner as the dRPA-
IIa case (consider the exchange of the matrices $K$ and $B$ in Eq. (23)).

As shown in Sec. 4, the approximate RPAX-Ia correlation energy expression leads to the most accurate results for the systems considered in this work. Additionally, while the RPAX-I approximation (Eq. 25) is known to suffer from instabilities when the initial states are approximated from semi-local functionals,\textsuperscript{33} the RPAX-Ia is numerically stable.

3 Computational realization

For the practical implementation, it is worth noting that spin-adaptation of all the equations is trivial: in spacial orbitals, the two-electron integrals read as $K_{ia,jb} = 2\langle ij|ab\rangle$, $A'_{ia,jb} = 2\langle ib|aj\rangle - \langle ib|ja\rangle$, $B_{ia,jb} = 2\langle ij|ab\rangle - \langle ij|ba\rangle$ and $\tilde{K}_{ia,jb} = \langle ij|ba\rangle$.

3.1 Orbital-based implementation

The computational realization of equations (14), (20) and (29) may proceed following a common scheme. In fact, Eq. (14) can be considered as a special case of Eq. (20), where $B = K$, and Eq. (29) can be obtained by interchanging the roles of $B$ and $K$ in Eq. (20). Therefore we focus our attention to the case of Eq. (20), i.e. the dRPA-IIa energy expression.

We can rewrite Eq. (20) in terms of the symmetric matrices $P(i\omega) = \Pi_0^{1/2}(i\omega)K\Pi_0^{1/2}(i\omega)$ and $\tilde{P}(i\omega) = \Pi_0^{1/2}(i\omega)\tilde{K}\Pi_0^{1/2}(i\omega)$ as

$$E_{\text{dRPA-IIa}} = \int_0^{\infty} \frac{d\omega}{2\pi} \text{tr}\left\{ \log(I - P(i\omega)) + P(i\omega) \times (I - P^{-1}(i\omega)\tilde{P}(i\omega)) \right\},$$

where we took advantage of the cyclic invariance of the trace and used the symmetry of $\Pi_0(i\omega)$ with respect to the replacement of $i\omega$ by $-i\omega$ to restrain the integral to the positive imaginary axis. The derivation of Eq. (30) also requires the following identity for a generic function of a matrix $f$: 

15
\[ f(\Pi_0^{1/2}K\Pi_0^{1/2}) = \Pi_0^{1/2}f(\Pi_0K)\Pi_0^{1/2}, \]  
\[ (31) \]

that can be easily derived from the matrix function formalism and from the fact that \( Q^{-1}\Pi_0KQ = D \) implies \( (Q^{-1}\Pi_0^{1/2})\Pi_0^{1/2}K\Pi_0^{1/2}(Q^{-1}Q) = U^T\Pi_0^{1/2}K\Pi_0^{1/2}U = D \) (the matrix \( U \) defines the unitary transformation that diagonalizes the Hermitian matrix \( \Pi_0^{1/2}K\Pi_0^{1/2} \)).

By expressing Eq. (30) in terms of the (diagonal) eigenvalue matrix \( D \) we obtain

\[
E_{\text{c}^{\text{dRPA-IIa}}} = \int_0^{\infty} \frac{d\omega}{2\pi} \tr \left\{ \left( \log(\mathbf{I} - D(i\omega)) + D(i\omega) \right) \times \left( \mathbf{I} - D^{-1}(i\omega)\tilde{D}(i\omega) \right) \right\},
\]

with \( \tilde{D}(i\omega) = U^T\tilde{P}(i\omega)U = (U^T\Pi_0^{1/2}(i\omega))\tilde{K}(\Pi_0^{1/2}(i\omega)U) = Q^{-1}\Pi_0(i\omega)\tilde{K}Q \). It should be emphasized that the matrix \( \tilde{P} \) has been transformed with the eigenvectors of \( P \) and therefore is not diagonal. Nevertheless in order to calculate the trace of its product with the diagonal matrix \( D^{-1} \) we need only its diagonal elements, which will be designated by the shorthand notation \( \tilde{a}_{ia}(i\omega) = [\tilde{D}(i\omega)]_{ia,ia} = [U^T\tilde{P}(i\omega)U]_{ia,ia} \).

The presence of potentially very small eigenvalues may lead to numerical instabilities. This can be avoided by using the following power series expansion of the logarithm under a given threshold of the eigenvalue \( d_{ia}(i\omega) \) (in practice, the summation is carried up to \( n = 4 \) and the threshold is 0.0001):

\[
E_{\text{c}^{\text{dRPA-IIa}}} \approx -\int_0^{\infty} \frac{d\omega}{2\pi} \sum_{ia}^{N_{\text{exc}}} \sum_{n=2}^{N_{\text{exc}}} \frac{1}{n} d_{ia}^{n-1}(i\omega) \left( d_{ia}(i\omega) - \tilde{a}_{ia}(i\omega) \right).
\]

(33)

At second order, \( n = 2 \), we obtain the MP2 energy, which can be designated as "Casimir-Polder transform MP2"
\[
E_{\text{c}}^{\text{MP2}} = -\frac{1}{2} \int_{0}^{\infty} \frac{d\omega}{2\pi} \sum_{ia}^{N_{\text{exc}}} d_{ia}(i\omega) \left( d_{ia}(i\omega) - \tilde{d}_{ia}(i\omega) \right),
\]

(34)

and which offers an interesting alternative to calculate conventional MP2 energies, especially in solids.\(^{44}\) Higher order terms of the series expansion do not correspond exactly to the MP3 and MP4 energies. A vague analogy can be noted between this expression and the Laplace-transform method to obtain the MP2 energy.\(^{25}\)

### 3.2 Density-based implementation of dRPA

The dRPA correlation energy can be brought to a computationally more efficient form by using density fitting (sometimes called resolution-of-identity) or Cholesky decomposition methods applied to the two-electron integrals. In these techniques the \((N_{\text{exc}} \times N_{\text{exc}})\) two-electron integral matrix is decomposed as (see also Appendix E)

\[
K_{ia,jb} = \left[ MM^T \right]_{ia,jb} = 2 \sum_{G} L_{ia,G} L_{G,jb},
\]

(35)

where \(M\) is a \((N_{\text{exc}} \times N_{\text{aux}})\) rectangular matrix, and \(N_{\text{aux}}\) is significantly smaller than \(N_{\text{exc}}\) (but larger than \(N_{\text{occ}} + N_{\text{virt}}\)). As shown in Appendix E, the correlation energy Eq. (14) becomes

\[
E_{c}^{\text{dRPA-I}} = \int_{0}^{\infty} \frac{d\omega}{2\pi} \text{tr}\{ \log (1 - C(i\omega)) + C(i\omega) \},
\]

(36)

where \(C(i\omega) = M^T \Pi_{0}(i\omega) M\) is a \((N_{\text{aux}} \times N_{\text{aux}})\) matrix and \(I\) is here the unit matrix of dimension \(N_{\text{aux}}\). Remembering that \(\Pi_{0}(i\omega) = -2\epsilon^{1/2}(\epsilon^2 + \omega^2)I^{-1}\epsilon^{1/2}\) it is easy to see that Eq. (36) is the same expression as the one obtained in an elegant but relatively involved manner by Eshuis et al.,\(^{25}\) starting from the plasmon expression of the correlation energy and the integral representation of
the square root of a matrix.

The density fitting technique can be generalized to the second order screened exchange correction in the dRPA-IIa correlation energy, leading to the following expression (see Appendix E)

\[
E_{c}^{dRPA-IIa} = \int_{0}^{\infty} \frac{d\omega}{2\pi} \text{tr} \left\{ (\log(1 - C(i\omega)) + C(i\omega)) \times (1 - C^{-1}(i\omega)Y(i\omega)C^{-1}(i\omega)) \right\},
\]

(37)

and the corresponding density fitting Casimir-Polder transform MP2 energy is obtained as the second-order contribution \((n = 2)\) in Eq. (37):

\[
E_{c}^{MP2} = -\frac{1}{2} \int_{0}^{\infty} \frac{d\omega}{2\pi} \text{tr} \left\{ C^{2}(i\omega) - Y(i\omega) \right\}.
\]

(38)

As shown in the Appendix E, the matrices \(C(i\omega)\) and \(Y(i\omega)\) are defined in terms of the matrices appearing in the decomposition of the two-electron integrals seen in Eq. (35) and of the orbital energy differences:

\[
C(i\omega) = 2 \sum_{i} X^{ii}(i\omega),
\]

(39)

and

\[
Y(i\omega) = 2 \sum_{ij} X^{ij}(i\omega)X^{ij}(i\omega),
\]

(40)

with
\[ [X^{ij}(i\omega)]_{PQ} = \sum_a L_{P,ia} \frac{-2\epsilon_{ia}}{\epsilon_{ia}^2 + \omega^2} L_{ja,Q}. \]  

(41)

In the density fitting case the working equations are similar to those in the orbital-based implementation. They can be obtained after diagonalization of the \( C(i\omega) \) matrix and take advantage of the fact that the dimensions \( (N_{aux} \times N_{aux}) \) of the matrix to be diagonalized is considerably smaller than \( N_{exc} \times N_{exc} \).

### 3.3 Numerical frequency integration

In principle, the numerical frequency integration is expected to be "fairly unproblematic",\(^{45}\) since the integrand is expected to have a smoothly decaying behavior. While it seems to be really the case for solids, where a mapping of the Gauss-Legendre quadrature to the \([0, \infty]\) interval (truncated at about 30 a.u.) with an exponentially decaying weighting function ensures a reasonable convergence (0.05 mH) with only 16 quadrature points,\(^{45}\) an accuracy of 0.2 mH (about 0.15 kcal/mol) claimed by the same authors is clearly insufficient for atoms and molecules. The situation for atomic and molecular systems is not better for more sophisticated weighting function models either.

Lu et al. have performed the frequency integration by a 10-point Gauss-Legendre quadrature in the range of \( u \in [0, 1] \), where \( u = (1 + \omega/\omega_0)^{-1} \), with \( \omega_0 = 1 \) a.u. This quadrature was found rather insensitive to the choice of the \( \omega_0 \) parameter.\(^9\)

We have implemented the method proposed by Eshuis, Yarkony and Furche,\(^{25}\) based on the Clenshaw-Curtis quadrature,\(^{46}\) which consists in writing the integral of a function \( F(\omega) \) as

\[ \int_0^\infty d\omega \ F(\omega) \approx \sum_p \frac{W_p}{2\pi} F(\omega_p), \]  

(42)
where $\omega_p = a \cot t_p$ with $t_p = p\pi/(2N_g)$ and $w_p = a\pi/((\text{int}(p/N_g) + 1)N_g \sin^2 t_p)$. This quadrature scheme has a single scaling parameter $a$, which can be adjusted to each individual system by requiring that the following analytically solvable expression, based on a diagonal model of the dRPA dielectric matrix formulation of Eq. (14) (remember that $\Pi_0(i\omega) = -2\epsilon^{1/2}\epsilon^2(\epsilon^2 + \omega^2)^{-1}\epsilon^{1/2}$):

$$
E_{c}^{\text{dRPA-I}} \approx \frac{1}{2} \sum_{ia} \int_{-\infty}^{\infty} \frac{d\omega}{2\pi} \left\{ \log \left( 1 + \frac{2\epsilon_{ia}K_{ia,ia}}{\epsilon_{ia}^2 + \omega^2} \right) - \frac{2\epsilon_{ia}K_{ia,ia}}{\epsilon_{ia}^2 + \omega^2} \right\} 
$$

$$
= -\frac{1}{2} \sum_{ia} \left( \epsilon_{ia} + K_{ia,ia} - \sqrt{\epsilon_{ia}^2 + 2\epsilon_{ia}K_{ia,ia}} \right),
$$

be reproduced at best by the numerical integral,

$$
E_{c}^{\text{dRPA-I}} \approx \sum_{ia} \sum_{p} w_p \sum_{ia} \frac{\epsilon_{ia} + K_{ia,ia} - \sqrt{\epsilon_{ia}^2 + 2\epsilon_{ia}K_{ia,ia}}}{2\pi}.
$$

This tuning method of the parameter $a$ can be extended for the dRPA-IIa case, using the analytically solvable dRPA-IIa diagonal approximation:

$$
E_{c}^{\text{dRPA-IIa}} \approx \frac{1}{2} \sum_{ia} \int_{-\infty}^{\infty} \frac{d\omega}{2\pi} \left\{ \log \left( 1 + \frac{2\epsilon_{ia}K_{ia,ia}}{\epsilon_{ia}^2 + \omega^2} \right) - \frac{2\epsilon_{ia}K_{ia,ia}}{\epsilon_{ia}^2 + \omega^2} \right\} 
$$

$$
\times \left\{ 1 - \frac{\tilde{K}_{ia,ia}}{K_{ia,ia}} \right\}
$$

$$
= -\frac{1}{4} \sum_{ia} \left\{ \epsilon_{ia} + K_{ia,ia} - \sqrt{\epsilon_{ia}^2 + 2\epsilon_{ia}K_{ia,ia}} \right\}.
$$

Note that the diagonal approximation to the dRPA-IIa correlation energy is half the diagonal approximation to the dRPA-I correlation energy seen in Eq. 43 (remember that in spatial orbitals we have $K_{ia,jb} = 2\langle \langle \langle \langle i\rangle \rangle \rangle$ and $\tilde{K}_{ia,jb} = \langle \langle \langle \langle i\rangle \rangle \rangle$) and there is no need to re-optimize the free parameter of the numerical quadrature.
4 Numerical results

We have implemented the dielectric matrix based dRPA-I (Eq. 14), dRPA-IIa (Eq. 20), and RPAX-Ia (Eq. 29) energy formulae in an occupied-virtual basis set representation within the development version of the MOLPRO quantum chemistry package.\textsuperscript{47,48} Although this algorithm is expected to be less efficient than the density fitting approach (in particular for larger systems), we considered this implementation useful to produce benchmark results exempt of density fitting uncertainties.

Below we present electron correlation energies for some atoms and ions\textsuperscript{49,50} and a test set of reaction energies.\textsuperscript{18} The correlation energy from the different RPA approximations $E_{\text{RPA}}^c$ has been calculated starting from a self-consistent DFT calculation based on the Perdew-Burke-Ernzerhof (PBE) exchange-correlation functional. The total RPA energy is then evaluated from the expression

\[
E_{\text{tot}}^{\text{RPA}} = E_{\text{EXX}} + E_{\text{c}}^{\text{RPA}},
\]

where $E_{\text{EXX}}$ is the Hartree-Fock energy computed from PBE orbitals.

For comparison purposes, we also provide results obtained from the rCCD-based SOSEX approximation\textsuperscript{11,43} and the dRPA-II approximation as derived within the adiabatic connection approach.\textsuperscript{33} As already discussed in Sec. 1 and Sec. 2.2 the dRPA-IIa (Eq. 20) and the rCCD-based SOSEX are analogous although not strictly equivalent; the numerical calculations below help to better quantify this statement. The dRPA-II approximation as derived within the adiabatic connection approach is equivalent to the dynamical polarizability expression in Eq. 17, that, however, cannot be conveniently implemented (both frequency and coupling constant integration are necessary and the dimensionality of the polarizability cannot be reduced). In this case the comparison between the dielectric matrix-based dRPA-IIa and the adiabatic connection-based dRPA-II is useful to understand the effect of the approximation of the kernel introduced by discarding the minor contribution to Eq. 18. To avoid confusion the dRPA-I, dRPA-IIa, and RPAX-Ia approximations derived within the dielectric matrix formulation will be denoted with an additional “DIEL”, the SOSEX approximation with an additional “rCCD”, and the dRPA-II approximation within the
adiabatic connection approach with an additional “AC”.

4.1 Frequency quadrature

The frequency integrations in Eqs. 14, 20 and 29 are carried out by a quadrature. We tested the convergence of the Gauss-Chebyshev, Gauss-Legendre and Clenshaw-Curtis schemes with respect to the number of quadrature points, for calculations on several atoms and ions. The RPA correlation energies were computed using the aug-cc-pCVXZ basis sets (X=6 for He, X=5 for Ne, Ar, B⁺, and Al⁺, and X=Q for Li⁺, Na⁺, Be, and Mg). The results of the convergence study can be found in Table 1 and Figure 1, where we use as reference the dRPA-
I PLASMON (for which both the frequency and coupling constant integrations are analytical, see Appendix B), and the dRPA-IIa AC and RPax-Ia AC energies (for which no PLASMON analog exists). We see that the Gauss-Chebyshev and Gauss-Legendre schemes yield, in this case, unsatisfying results: the Gauss-Chebyshev scheme has a slow convergence with respect to the number of quadrature points in all the cases studied, and while the Gauss-Legendre quadrature performs well for Be, He and Li\(^+\), it exhibits a slow convergence in the cases of B\(^+\), Mg and Na\(^+\). On the other hand, the Clenshaw-Curtis quadrature was found to converge rapidly for all studied atoms and ions. As a result, we choose in the following to perform the frequency integration with a 48-points Clenshaw-Curtis quadrature.

Table 1: Errors made in the calculation of the dRPA-I DIEL energy using 24-, 48-, 72- and 96-points Gauss-Chebyshev, Gauss-Legendre and Clenshaw-Curtis quadrature schemes (in percentage with respect to the dRPA-I PLASMON result).

4.2 Atomic correlation energies

As a first test, we applied the dielectric matrix formalism to compute correlation energies for several atoms and ions. To verify the accuracy of the RPA-based approximations we compared the
Figure 2: Percentage error of total correlation energies compared to the FCI-quality estimates by
Davidson and his coworkers\textsuperscript{49,50} for simple closed shell atoms and ions calculated with different
RPA variants. Correlation energies have been extrapolated to the CBS limit.
obtained results with the full configuration interaction (FCI) quality correlation energy estimates by Davidson and collaborators.\textsuperscript{49,50} For a meaningful comparison it is necessary to keep into account that the FCI-quality correlation energies have been obtained with respect to a Hartree-Fock reference point. For this reason we redefined the RPA correlation energies $\tilde{E}_{c}^{\text{RPA}}$ as the difference of RPA total energies and regular Hartree-Fock energies. This procedure was already used in Ref. 33. Core excitations have been included in the calculations. The RPA-based correlation energies were computed in the complete basis set (CBS) limit by the usual $1/X^3$ formula\textsuperscript{51} considering aug-cc-pCVXZ basis sets up to $X=6$ for He, up to $X=5$ for Ne, Ar, B\textsuperscript{+}, and Al\textsuperscript{+}, and up to $X=Q$ for Li\textsuperscript{+}, Na\textsuperscript{+}, Be, and Mg. The ratios between the RPA-based correlation energies $\tilde{E}_{c}^{\text{RPA}}$ and reference FCI correlation energies $E_{c}^{\text{FCI}}$ are shown in Fig. 2. As expected the dRPA-I DIEL approximation strongly overestimates the absolute value of the correlation energy (by 50 to 100 \%). On the other hand, the dRPA-IIa DIEL and RPax-Ia DIEL approximations, which include exchange contributions, significantly improve the direct RPA results and lead to a percentage of the correlation energy close to 100 \%. On the scale of Fig. 2 the dRPA-IIa DIEL and SOSEX rCCD results are basically indistinguishable (the largest difference is found for Al\textsuperscript{+}, where SOSEX rCCD gives 95.79\% of the FCI correlation energy and dRPA-IIa 95.57\%). The dRPA-II AC, which does not rely on the neglect of the minor contribution to the kernel discussed in Eq. 18, provides the worst results among the approximations including exchange effects.

### 4.3 Application to reaction energies

In this section we discuss a series of results for the reaction energy test set proposed by Hesselmann.\textsuperscript{18} In this case the accuracy is evaluated with respect to CCSD(T) benchmark results; CCSD values are also provided for comparison purposes. Similarly to Ref. 18, the correlation energy in the complete basis set limit is obtained by extrapolating the values obtained with the aug-cc-pVTZ and aug-cc-pVQZ basis sets. Reaction energy results are detailed in Table 2 for the different approximations considered in this work. The simple dRPA-I DIEL approximation gives substantial mean error (ME) and mean absolute error (MAE): 2.18 kcal/mol and 2.32 kcal/mol, respectively.
The dRPA-IIa DIEL approach, with a MAE of 1.99 kcal/mol and a ME of -1.43 kcal/mol, improves to a certain extent the results of dRPA-I DIEL. Table 2 also shows that dRPA-IIa and SOSEX produce similar results, with a difference of at most 0.2 kcal/mol. The use of the full exchange kernel (Eq. 18), as done in dRPA-II AC, deteriorates the accuracy and leads to a MAE that is even larger than in the case of the simple dRPA-I approach. We finally consider the RPax-Ia DIEL approximation. The corresponding MAE and ME are significantly decreased with respect to the other methods and close to CCSD values. Considering these results for reaction energies and the previous results for atoms and ions in Sec. 4.2, we can notice that the RPax-Ia approach is the most promising within the dielectric matrix approximations studied in this work. Additionally, RPax-Ia is more stable than RPax-I (Eq. 25) when using PBE as starting point. \(^{33}\)
Table 2: Reaction energies for 16 chemical reactions (in kcal/mol). The mean error (ME) and mean absolute error (MAE) are computed with respect to CCSD(T)/CBS. The results with the smallest deviation from the benchmark value are marked in bold face.

The reaction test set in Table 2 involves only energy differences between molecular energies. To better understand the performance of each method it is interesting to also discuss the total energy of each molecule. Detailed results are summarized in Table 3, where the deviation of the total energy of each molecule from CCSD(T) reference values is presented. Since an error cancellation is expected when energy differences are computed, it is not surprising that the approximations in Table 3 lead to MEs and MAEs with respect to CCSD(T) that are substantially larger than what previously seen in Table 2. For total energies the dRPA-I approximation leads to the largest deviation with a MAE of about 168 kcal/mol. The dRPA-IIa DIEL, the SOSEX rCCD, and the dRPA-II AC approximations all have a considerably lower MAE (about 30 kcal/mol). However, it is important to notice that dRPA-II AC tends to overestimate the total energy while dRPA-IIa DIEL and SOSEX rCCD underestimate it. Considering Table 3, the method that gives the most accurate results is RPAx-Ia DIEL, which provides a MAE of less than 9 kcal/mol and outperforms CCSD.

![Figure 3](image-url)

Figure 3: Relative error of the total energy computed with different RPA methods with respect to CCSD(T)/CBS results.
Table 3: Differences between total energies computed within different approximations and CCSD(T)/CBS reference values (in kcal/mol). Mean error (ME) and mean absolute error (MAE) of total energies are included in the table. The results are presented for the 21 molecules involved in the reactions considered in Table 2 (in kcal/mol). The molecules are sorted in increasing order of the absolute values of CCSD(T) total energies.

</table>
To help the visualization of the results in Table 3, we show in Fig. 3 the relative error of total energies obtained within different RPA approximations with respect to CCSD(T) results. The dRPA-I DIEL approximation leads to substantially larger errors and, in order to make the graph more readable, has not been included in the figure. The trend of the curves shows that the relative error tends to be approximately constant by increasing the molecular size. Since CCSD/CBS is exact for two-electron systems it is not surprising that the corresponding relative error for H₂ is zero. For all the other methods H₂ is instead the most problematic case, which is related to the fact that the reference determinant is constructed from PBE orbitals. The dRPA-IIa DIEL and SOSEX rCCD approximations give almost identical curves for all the molecules considered here (the difference is at most 1.2 kcal/mol, for NH₂CONH₂ and HCOOCH₃). With the exception of H₂, the RPAx-Ia relative error is systematically lower than in the CCSD case. However, as seen in Table 2, the accuracy of RPAx-Ia slightly worsens with respect to CCSD in the case of reaction energies, whose evaluation takes advantage of an error cancellation effect.

5 Conclusions, perspectives

The main result of the present work is to show that in contrast to a widely accepted view it is possible to conveniently include exchange effects in the dielectric matrix formulation of RPA correlation energy. Two particular cases have been derived and numerically implemented: the SOSEX-like dRPA-IIa correlation energy and an approximate variant of the RPAx-I method, named RPAx-Ia. Our derivation of the dielectric matrix formulation of the RPA proceeds in a "conventional" or "traditional" way, i.e. from the full adiabatic connection formula at an RPA level. This is in contrast to the work of Eshuis and Furche, who started from the plasmon formula of the dRPA-I energy and derived directly the density fitting expressions. Our approach is strictly equivalent to theirs for dRPA-I but offers in addition a well-defined route to get alternative variants including exchange in a similar form. Furthermore, the connections with the previously studied density matrix formulation are straightforwardly established and therefore our previous results concerning the relationship
between the adiabatic connection and rCCD RPA can be simply transferred.

We think that the main interest of the dielectric matrix formalism of RPA in a quantum chemical (more precisely LCAO based) context is mostly conceptual. As demonstrated by the work of Eshuis and Furche, this formalism is well-adapted for density fitting implementations, which is computationally advantageous, in particular for the dRPA-I case, which is an $O(N^4 \log(N))$ method. The exchange-including variants are expected to show a somewhat less advantageous $O(N^5 \log(N))$ behavior which is comparable to the scaling of DF-MP2\textsuperscript{52} or RI-MP2.\textsuperscript{53,54} The brute-force orbital-based implementations are of $O(N^6)$ scaling.

It is important to notice the new approximations developed within this work may be of significant interest for the condensed matter physics community, that mostly rely on the dielectric matrix formalism to compute RPA correlation energies.\textsuperscript{3,6,8,9,12,23}

As shown in this work, the relatively poor performance of the dRPA-I is improved to a certain extent by the dRPA-IIa (SOSEX-like) method. The approximate RPax-Ia approach is surprisingly good for the systems considered in this paper. In the future more test cases will certainly be necessary to fully establish the accuracy of the RPax-Ia method. Additionally, this methodology is suitable for implementation in plane-wave codes\textsuperscript{23} and applications to solids will be soon possible.

The authors thank Andreas Hesselmann for useful discussions and for providing data on the molecular reaction test set. Computer time was provided by GENCI-CCRT/CINES under grant x2015-085106.

A Equivalence of the density matrix and logarithmic expressions

In this appendix we show the equivalence of the density matrix and logarithmic expressions of the dRPA-I correlation energies described in this paper. The derivation holds for dRPA-IIa, by
replacing $K$ with $B$. Let us recall Eq. (12) as:

$$ E_{\text{dRPA-I}}^c = -\frac{1}{2} \int_0^1 d\alpha \int_{-\infty}^{\infty} d\omega \frac{1}{2\pi} \text{tr}\{ \Pi_\alpha(i\omega)K - \Pi_0(i\omega)K \}. \quad (47) $$

Since

$$ \Pi_0(i\omega) = \Pi_0^+(i\omega) + \Pi_0^-(i\omega) = -2\epsilon^{1/2}(\epsilon^2 + \omega^2 I)^{-1}\epsilon^{1/2}, \quad (48) $$

from the "dimension-reduced" Dyson equation $\Pi_\alpha^{-1}(i\omega) = \Pi_0^{-1}(i\omega) - \alpha K$, we have

$$ \Pi_\alpha^{-1}(i\omega) = -\frac{1}{2}\epsilon^{-1/2}(M_\alpha + \omega^2 I)\epsilon^{-1/2}, \quad (49) $$

where

$$ M_\alpha = \epsilon^{1/2}(\epsilon + 2\alpha K)\epsilon^{1/2}. \quad (50) $$

The symmetric matrix $M_\alpha$ can be brought to a diagonal form using its eigenvectors and eigenvalues:

$$ M_\alpha Z_\alpha = Z_\alpha \Omega_\alpha^2, \quad Z_\alpha Z_\alpha^T = Z_\alpha^T Z_\alpha = I. \quad (51) $$

Thus we find:
\[
\Pi_{\alpha}^{-1}(i\omega) = -\frac{1}{2} \epsilon^{-1/2} Z_\alpha Z^\top_\alpha (M_\alpha + \omega^2 I) Z_\alpha Z^\top_\alpha \epsilon^{-1/2} \\
= -\frac{1}{2} \epsilon^{-1/2} Z_\alpha (\Omega_\alpha^2 + \omega^2 I) Z^\top_\alpha \epsilon^{-1/2},
\] (52)

and furthermore:

\[
\Pi_{\alpha}(i\omega) = -2 \epsilon^{1/2} Z_\alpha (\Omega_\alpha^2 + \omega^2 I)^{-1} Z^\top_\alpha \epsilon^{1/2}.
\] (53)

Noting that

\[
\int_{-\infty}^{\infty} d\omega \frac{\omega}{2\pi} (\Omega_{\alpha,ia}^2 + \omega^2)^{-1} = \frac{1}{2} \Omega_{\alpha,ia}^{-1},
\] (54)

where \( ia \) labels the eigenvalues of \( M_\alpha \), \textit{i.e.} the diagonal elements of \( \Omega \), we get

\[
\int_{-\infty}^{\infty} d\omega \frac{\omega}{2\pi} \Pi_{\alpha}(i\omega) = -\epsilon^{1/2} Z_\alpha \Omega_\alpha^{-1} Z^\top_\alpha \epsilon^{1/2} = -\epsilon^{1/2} M_\alpha^{-1/2} \epsilon^{1/2}.
\] (55)

Furthermore, since \( M_0 = \epsilon^2 \), we have

\[
\int_{-\infty}^{\infty} d\omega \frac{\omega}{2\pi} \Pi_0(i\omega) = -\epsilon^{1/2} \epsilon^{-1} \epsilon^{1/2} = -I,
\] (56)

which finally leads to

33
\[ E^{\text{dRPA-I}} = \frac{1}{2} \int_0^1 d\alpha \ P_{c,\alpha} K, \]  
with

\[ P_{c,\alpha} = \epsilon^{1/2} M_{\alpha}^{-1/2} \epsilon^{1/2} \mathbf{1}. \]

This derivation demonstrates the equivalence of the density matrix and dielectric matrix formulations of the dRPA-I (and \textit{mutatis mutandis}, of the dRPA-IIa) energy expressions.

**B Plasmon formula**

Starting from Eq. (14), we re-write the argument of the logarithm by using the "dimension-reduced" Dyson equation in the following form:

\[ \mathbf{I} - \Pi_0(i\omega) K = \Pi_0(i\omega) \Pi_1^{-1}(i\omega). \]  

Combining Eqs.(48) and (52), one obtains

\[ \Pi_0(i\omega) \Pi_1^{-1}(i\omega) = \epsilon^{1/2} (\epsilon^2 + \omega^2 \mathbf{1})^{-1} Z_1(\Omega_1^2 + \omega^2 \mathbf{1}) Z_1^T \epsilon^{-1/2}. \]

Employing \( \text{tr} \{ \log(X) \} = \log \{ \det(X) \} \) and properties of the determinant leads to:
\[
\text{tr} \left\{ \log \left( \Pi_0(i\omega) \Pi_1^{-1}(i\omega) \right) \right\} \\
= \log \left\{ \det \left( (\epsilon^2 + \omega^2 I)^{-1} (\Omega_1^2 + \omega^2 I) \right) \right\} \\
= \sum_{ia} \log \left( \frac{\Omega_{1,ia}^2 + \omega^2}{\epsilon_{ia}^2 + \omega^2} \right) = \sum_{ia} \log \left( 1 + \frac{\Omega_{1,ia}^2 - \epsilon_{ia}^2}{\epsilon_{ia}^2 + \omega^2} \right). \tag{61}
\]

For the evaluation of the trace of \( \Pi_0(i\omega) K \) we use the definition of \( M_1 \) to write \( K = \frac{1}{2} \epsilon^2 e^{-1/2} (M_1 - \epsilon^2) e^{-1/2} \) and we obtain

\[
\text{tr} \left\{ \Pi_0(i\omega) K \right\} = -\text{tr} \left\{ (\epsilon^2 + \omega^2 I)^{-1} \left( M_1 - \epsilon^2 \right) \right\}. \tag{62}
\]

Summarizing, one finally obtains:

\[
E_{c}^{\text{dRPA-I}} = \frac{1}{2} \int_{-\infty}^{\infty} d\omega \frac{1}{2\pi} \sum_{ia} \left\{ \log \left( 1 + \frac{\Omega_{ia}^2 - \epsilon_{ia}^2}{\epsilon_{ia}^2 + \omega^2} \right) - \frac{M_{1,ia,ia} - \epsilon_{ia}^2}{\epsilon_{ia}^2 + \omega^2} \right\}, \tag{63}
\]

which, after integration (see Appendix C), becomes

\[
E_{c}^{\text{dRPA-I}} = \frac{1}{2} \left\{ \sum_{ia} \Omega_{ia} - \sum_{ia} (\epsilon_{ia} + K_{ia,ia}) \right\}. \tag{64}
\]

C Background of complex integration

Using the method followed by McLachlan et al.\textsuperscript{41} the frequency integral in Eq. (63) can be solved via an integration by parts of the logarithm and by invoking the argument principle, leading to the result of Eq. (64) after contour integration. To explain these steps, a review of some complex integration notions is presented. A comprehensive account on the subject can be found in Ref.\textsuperscript{35}.
Figure 4: \( \Omega \) is a region with holes \( A_1, A_2, \ldots, A_n, A_{n+1} \) (\( A_{n+1} \) is the "exterior" of \( \Omega \)). We have: \( \gamma_1 \sim 0[\Omega] \), i.e. the closed curve does not wind around any point that is outside of \( \Omega \). And: \( \gamma_2 \sim \gamma_3[\Omega] \), i.e. the two closed curves wind around all the points outside of \( \Omega \) in the same manner.

An important notion to consider when dealing with complex integration is the index of a point \( a \) with respect to a closed curve \( \gamma \), denoted \( n(\gamma, a) \). In layman’s terms, it indicates how many times a closed curve winds around a point not on the curve, and is defined as:

\[
n(\gamma, a) = \frac{1}{2\pi i} \int_{\gamma} \frac{dz}{z - a}. \quad (65)
\]

Having defined the notion of index, a property of the closed curves emerges: the homology. In simple words, considering a region \( \Omega \) with holes \( A_1, A_2, \ldots, A_n, A_{n+1} \), such as in Fig. (4), we say that closed curves \( \gamma_i \) and \( \gamma_j \) are homologous with respect to \( \Omega \) when they wind around every point outside of \( \Omega \) the same number of times (this is written \( \gamma_i \sim \gamma_j[\Omega] \)). In Fig. (4), the closed curves \( \gamma_2 \) and \( \gamma_3 \) are homologous with respect to \( \Omega \).

For any region \( \Omega \) like seen in Fig. (4), we are able to construct an homology basis as a set of closed curves \( \{\gamma_i\} \) around the holes \( A_i \) of \( \Omega \), such that for any closed curve \( \gamma \):

\[
\gamma \sim (c_1\gamma_1 + c_2\gamma_2 + \cdots + c_n\gamma_n)[\Omega], \quad (66)
\]
where the $c_i$ are the (constant) indexes $n(\gamma, a_i)$ of the points $a_i$ in a hole $A_i$.

In particular, considering a function $f$ analytic in the whole region except for isolated poles $a_1, a_2, \ldots, a_n$ that lay inside the holes $A_1, A_2, \ldots, A_n$ ($f$ is said to be meromorphic), Cauchy’s theorem yields that:

$$\int_{\gamma} f \, dz = c_1 \int_{\gamma_1} f \, dz + c_2 \int_{\gamma_2} f \, dz + \cdots + c_n \int_{\gamma_n} f \, dz = 2\pi i (c_1 R_1 + c_2 R_2 + \cdots + c_n R_n), \quad (67)$$

which defines the $R_i$, the residues of $f$ at point $a_i$. Equation (67) is called the residue theorem.

An application of the residue theorem, called the argument principle is of particular interest for us. For any meromorphic function $f$ with zeros $a_i$ of order $h_i$ and poles $b_j$ of order $h_j$, the function $f' / f$ has simple poles $a_i$ and $b_j$ of residues $h_i$ and $-h_j$. Application of the residue theorem to $f' / f$ gives:

$$\frac{1}{2\pi i} \int_{\gamma} \frac{f'(z)}{f(z)} \, dz = \sum_i n(\gamma, a_i) h_i - \sum_j n(\gamma, b_j) h_j. \quad (68)$$

This is the argument principle, which can be generalized to a function $g \times (f'/f)$:

$$\frac{1}{2\pi i} \int_{\gamma} g(z) \frac{f'(z)}{f(z)} \, dz = \sum_i n(\gamma, a_i) g(a_i) h_i - \sum_j n(\gamma, b_j) g(b_j) h_j. \quad (69)$$

Note that one will often find the argument principle written with a convention where the summation over the zeros and poles are repeated as many times as their order indicates, which allows a more compact expression:
\[
\frac{1}{2\pi i} \int g(z) \frac{f'(z)}{f(z)} \, dz = \sum_i n(\gamma, a_i) g(a_i) \\
- \sum_j n(\gamma, b_j) g(b_j).
\] (70)

Having this in mind, let us introduce a change of variable \( \omega = i \xi \) in Eq. (63):

\[
E_c^{\text{dRPA-I}} = \frac{1}{2} \int_{-\infty}^{\infty} \frac{d\xi}{2\pi i} \sum_{ia} \left\{ \log \left( 1 + \frac{\Omega_{ia}^2 - \epsilon_{ia}^2}{\epsilon_{ia}^2 - \xi^2} \right) - \frac{M_{1,ia,ia} - \epsilon_{ia}^2}{\epsilon_{ia}^2 - \xi^2} \right\}.
\] (71)

The second term integrates to \(-K_{ia,ia}\), and the logarithm can be integrated by parts:

\[
\frac{1}{2\pi i} \int \log(f(z)) \, dz = -\frac{1}{2\pi i} \left[ \log(f(z)) \, z \right] + \frac{1}{2\pi i} \int \frac{f'(z)}{f(z)} \, z
\]
\[
= \sum_i a_i - \sum_j b_j.
\] (72)

The first term vanishes since \( \lim_{z \to \pm\infty} \log(f(z)) z = 0 \) and we have applied the argument principle to the second term, with a contour chosen so that all indexes are equal to one. The zero of our function \( f \) is \( \Omega_{ia} \), its pole is \( \epsilon_{ia} \), hence the final expression:

\[
E_c^{\text{dRPA-I}} = \frac{1}{2} \left\{ \sum_{ia} \Omega_{ia} - \sum_{ia} (\epsilon_{ia} + K_{ia,ia}) \right\}.
\] (73)

(This is because in the particular case of simples poles in \( a_i \), the residues take the value of \((z-a_i)f(z)\) for \( z = a_i \)).
Proof of vanishing second-order contributions in the derivation of dRPA-IIa from dRPA-II

The minor correction to the integrand of Eq. (17) directly reads as (without the unitary transformation used for the major contribution):

$$\alpha \text{tr}\left\{ (I - \alpha \Pi_0 K)^{-1} (\Pi_0^+ K \Pi_0^+ + \Pi_0^- K \Pi_0^-)(A' - B) \right\}. \quad (74)$$

We consider the matrix identity

$$(I - \alpha \Pi_0 K)^{-1} = I + \alpha (I - \alpha \Pi_0 K)^{-1} \Pi_0 K$$

$$= Q \left[ I + \alpha (I - \alpha D)^{-1} D \right] Q^{-1}, \quad (75)$$

where the diagonal matrix $D(i\omega)$ contains the eigenvalues of $\Pi_0(i\omega)K$, and the matrix $Q(i\omega)$ it’s eigenvectors. The contribution coming from the identity term in the second member of Eq. (75) dominates over the contribution coming from the second term. Indeed, since $-\alpha d_{ia} > 0$ ($d_{ia}$ being the diagonal elements of $D$), we have that $|\alpha d_{ia}/(1 - \alpha d_{ia})| < 1$. Furthermore, since $d_{ia}$ decreases rapidly to small values as a function of the index $ia$ and of $i\omega$, we can assume that $|\alpha d_{ia}/(1 - \alpha d_{ia})| \ll 1$ for most $ia$’s.

By virtue of this, we include only the first contribution to Eq. (75), $I$, in Eq. (74), and we are left with the task of proving that:

$$\int_{-\infty}^{\infty} \frac{d\omega}{2\pi} (\Pi_0^+(i\omega) K \Pi_0^+(i\omega) + \Pi_0^-(i\omega) K \Pi_0^-(i\omega)) = 0. \quad (76)$$

We first note that:
\[ \int_{-\infty}^{\infty} \frac{d\omega}{2\pi} \text{tr}[\Pi^+_0(i\omega)K\Pi^-_0(i\omega)] = \int_{-\infty}^{\infty} \frac{d\omega}{2\pi} \text{tr}[\Pi^+_0(i\omega)K\Pi^-_0(i\omega)], \quad (77) \]

which may be seen by replacing \( \omega \) with \(-\omega\), adapting the integration limits and noting that \( \Pi^-_0(-i\omega) = \Pi^+_0(i\omega) \). Now with

\[ [\Pi^+_0(i\omega)K\Pi^-_0(i\omega)]_{ia,jb} = \frac{K_{ia,jb}}{(i\epsilon_{ia} + \omega)(i\epsilon_{jb} + \omega)}, \quad (78) \]

one can see that the denominator of each of these integrals has simple poles at \( \omega = -i\epsilon_{ia} \) and \( \omega = -i\epsilon_{jb} \) if \( \epsilon_{ia} \neq \epsilon_{jb} \) and a twofold pole otherwise. In any case it has no poles on the positive imaginary axis. Replacing \( \omega \) by a complex number \( z \) and choosing an integration contour \( \Gamma \) which passes along the real axis from \(-\infty\) to \( \infty \) and encircles the complex half-plane with positive imaginary values in a counter-clockwise way and finally noting that the integrand vanishes quadratically for large \( |z| \), it follows from the residue theorem that:

\[ \int_{-\infty}^{\infty} \frac{d\omega}{2\pi} \frac{1}{(i\epsilon_{ia} + \omega)(i\epsilon_{jb} + \omega)} = \int_{\Gamma} \frac{dz}{2\pi} \frac{1}{(i\epsilon_{ia} + z)(i\epsilon_{jb} + z)} = 0. \quad (79) \]

For the case \( \epsilon_{ia} = \epsilon_{jb} \) the integral trivially vanishes since the integrand then corresponds to a member of order \(-2\) in a Laurent series.

E **Density fitting**

Let us start from the expression for the ACFDT dRPA-IIa correlation energy of Eq. (21) for a closed shell system, using spatial orbitals
\[ E_{c}^{\text{dRPA-IIa}} = \frac{1}{2} \int_{-\infty}^{\infty} d\omega \frac{\omega}{2\pi} \text{tr} \left\{ \log (I - \Pi_{0}(i\omega)K) + \Pi_{0}(i\omega)K \right\} \times \left( 1 - (\Pi_{0}(i\omega)K)^{-1}\Pi_{0}(i\omega)\tilde{K} \right), \tag{80} \]

where (in chemist’s notation) \( K_{ia,jb} = 2(ia|jb) \) and \( \tilde{K}_{ia,jb} = (ib|ja) \). The non-interacting response function explicitly reads as

\[ [\Pi_{0}(i\omega)]_{i,j,a} = \frac{-2\epsilon_{ia}\delta_{ij}\delta_{ab}}{\epsilon_{ia}^{2} + \omega^{2}}, \tag{81} \]

while the density fitting expression for the two types of two-electron integrals may be written as

\[ K_{ia,jb} = [MM^{T}]_{ia,jb} = \sum_{G} M_{ia,G} M_{G,jb} = 2 \sum_{G} L_{ia,G} L_{G,jb} \tag{82} \]
\[ \tilde{K}_{ia,jb} = [NN^{T}]_{ia,jb} = \sum_{G} N_{ia,G} N_{G,jb} = \sum_{G} L_{ib,G} L_{G,ja}. \tag{83} \]

With these expressions, the first contribution to Eq. (80) corresponding to \( E_{c}^{\text{dRPA-I}} \) can be written as

\[ \text{tr} \left\{ \log (I - \Pi_{0}(i\omega)K) + \Pi_{0}(i\omega)K \right\} \]
\[ = \text{tr} \left\{ \log \left( I - \Pi_{0}(i\omega)MM^{T} \right) + \Pi_{0}(i\omega)MM^{T} \right\} \]
\[ = \text{tr} \left\{ \log \left( I - M^{T}\Pi_{0}(i\omega)M \right) + M^{T}\Pi_{0}(i\omega)M \right\} \]
\[ = \text{tr} \left\{ \log (I - C(i\omega)) + C(i\omega) \right\}, \tag{84} \]

where we used the cyclic invariance of the trace and the fact that the non-zero eigenvalues of
\( \Pi_0(i\omega)MM^T \) and \( M^T \Pi_0(i\omega)M \) are identical. We defined:

\[
C_{PQ}(i\omega) = [M^T \Pi_0(i\omega)M]_{PQ} = \sum_{\alpha} L_{p,\alpha} \frac{-4\epsilon_{\alpha} - \omega^2 L_{\alpha,\alpha}}{\epsilon_{\alpha}}.
\] (85)

The exchange ("SOSEX-like") contribution to Eq. (80) is more complicated. In order to keep the notation as simple as possible we define the function \( g \) of a generic matrix \( A \) as

\[
g(A) = [\log (I - A) + A]A^{-1}.
\] (86)

In this definition we intend \( A^{-1} \) as a pseudoinverse that does not include the contribution from (almost) zero eigenvalues, as discussed in Sec. 2.2; by passing to the density fitting or Cholesky representation a possible linear dependence of the matrix \( A \) is removed and the inverse of \( A \) is well defined and coincides with its pseudoinverse.

We can express the exchange contribution as

\[
\text{tr} \left\{ (\log (I - \Pi_0(i\omega)K) + \Pi_0(i\omega)K)(\Pi_0(i\omega)K)^{-1}\Pi_0(i\omega)\tilde{K} \right\}
\]

\[
= \text{tr} \left\{ g(\Pi_0(i\omega)K)\Pi_0(i\omega)\tilde{K} \right\}
\]

\[
= \text{tr} \left\{ M^T g(\Pi_0(i\omega)MM^T)\Pi_0(i\omega)\Pi_0(i\omega)NN^T(MM^T)^{-1}M \right\},
\] (87)

where we multiplied by \( I = (MM^T)^{-1}MM^T \). The following identity (demonstrated in Appendix F):

\[
\text{tr} \left\{ M^T g(\Pi_0(i\omega)MM^T) B \right\} = \text{tr} \left\{ g(M^T \Pi_0(i\omega)M) M^T B \right\},
\] (88)

allows us to further derive:
\[
\text{tr}\left\{\log (I - \Pi_0(i\omega)K) + \Pi_0(i\omega)K (\Pi_0(i\omega)K)^{-1} \Pi_0(i\omega){\tilde K}\right\}
\]
\[
= \text{tr}\left\{g(M^T\Pi_0(i\omega)M) M^T\Pi_0(i\omega)NN^TM^T)^{-1} M\right\}
\]
\[
= \text{tr}\left\{(M^T\Pi_0(i\omega)M)^{-1} g(M^T\Pi_0(i\omega)M) \times M^T\Pi_0(i\omega)NN^TM^T)^{-1} M^T\Pi_0(i\omega)M\right\}
\]
\[
= \text{tr}\left\{C(i\omega)^{-1} g(C(i\omega)) M^T\Pi_0(i\omega)NN^T\Pi_0(i\omega)M\right\},
\]
(89)

where we multiplied by \(1 = M^T\Pi_0(i\omega)M(M^T\Pi_0(i\omega)M)^{-1}\), applied the definition of \(C(i\omega)\) and resolved the inverse. The last matrix products under the trace read:

\[
\left[ M^T\Pi_0(i\omega)NN^T\Pi_0(i\omega)M \right]_{QP} =
\]
\[
= \sum_{ia,jb} \sum_G \left( M_{Q,ia} \frac{-2\epsilon_{ia}}{\epsilon_{ia}^2 + \omega^2} N_{ia,G} \right) \left( N_{G,jb} \frac{-2\epsilon_{jb}}{\epsilon_{jb}^2 + \omega^2} M_{jb,P} \right)
\]
\[
= 2 \sum_{ia,jb} \sum_G \left( L_{Q,ia} \frac{-2\epsilon_{ia}}{\epsilon_{ia}^2 + \omega^2} L_{ib,G} \right) \left( L_{G,ja} \frac{-2\epsilon_{jb}}{\epsilon_{jb}^2 + \omega^2} L_{jb,P} \right)
\]
\[
= 2 \sum_{ij} \sum_G \left( \sum_a L_{Q,ia} \frac{-2\epsilon_{ia}}{\epsilon_{ia}^2 + \omega^2} L_{ja,G} \right) \left( \sum_b L_{G,ib} \frac{-2\epsilon_{jb}}{\epsilon_{jb}^2 + \omega^2} L_{jb,P} \right),
\]
(90)

By introducing the quantities

\[
[X^{ij}(i\omega)]_{QG} = \sum_a L_{Q,ia} \frac{-2\epsilon_{ia}}{\epsilon_{ia}^2 + \omega^2} L_{ja,G},
\]
(91)

and
\[ Y(i\omega) = 2 \sum_{ij} X^{ij}(i\omega)X^{ij}(i\omega), \]  

(92)

and remembering the definition of the matrix function \( g \) in Eq. (86), the general exchange term in Eq. (90) can be written as

\[ \text{tr}\left\{ (\log(I - C(i\omega)) + C(i\omega))C^{-1}(i\omega)Y(i\omega)C^{-1}(i\omega) \right\}. \]  

(93)

We note that \( C(i\omega) \) can be defined from the "diagonal elements" of the \( X^{ij}(i\omega) \) super-matrices:

\[ C_{PQ}(i\omega) = \sum_{ia} L_{Pia} \frac{-4\epsilon_{ia}}{\epsilon_{ia}^2 + \omega^2} L_{ia,Q} = 2 \sum_{i} X^{ii}_{PQ}(i\omega). \]  

(94)

Combining everything together the density-fitting dRPA-IIa correlation energy in Eq. (80) finally becomes:

\[ E_{\text{c-dRPA-IIa}} = \int_{0}^{\infty}d\omega \frac{1}{2\pi} \text{tr}\left\{ (\log(I - C(i\omega)) + C(i\omega)) \times \right. \]

\[ \left. (I - C^{-1}(i\omega)Y(i\omega)C^{-1}(i\omega)) \right\}. \]  

(95)

**F  Proof of Eq. (89)**

In order to derive the final result of Appendix E it is necessary to demonstrate the validity of the equation (in order to keep the notation simple, the explicit dependence of \( \Pi_0 \) on \( i\omega \) has been dropped):
\[
\text{tr}\left\{ M^T g(\Pi_0 MM^T) B \right\} = \text{tr}\left\{ g(M^T \Pi_0 M) M^T B \right\}, \tag{96}
\]

where \( B = \Pi_0 NN^T (MM^T)^{-1} M \) is the \((N_{\text{exc}} \times N_{\text{aux}})\) matrix seen in Eq. (88) and \( MM^T \) denotes the Cholesky decomposition in Eq. (82). By remembering that a generic function of a matrix is defined as \( f(A) = Q f(D) Q^{-1} \), we have

\[
\text{tr}\left\{ M^T g(\Pi_0 MM^T) B \right\} = \\
\sum_{G} \sum_{ia,jb,kc} M_{G,ia} \sum_{ia,kc} Q_{ia,kc} g(d_{kc}) Q^{-1}_{kc,jb} B_{jb,G}. \tag{97}
\]

From the definition of the function \( g \) in Eq. (86) we have that \( g(0) = 0 \), namely the zero (or below a certain threshold) eigenvalues \( d_{kc} \) do not contribute to Eq. (98), that can be rewritten as

\[
\text{tr}\left\{ M^T g(\Pi_0 MM^T) B \right\} = \\
\sum_{G} \sum_{ia,jb} \sum_{kc} N_{\text{eig}} M_{G,ia} \sum_{ia,kc} Q_{ia,kc} g(d_{kc}) Q^{-1}_{kc,jb} B_{jb,G}. \tag{98}
\]

where \( N_{\text{eig}} \) indicate that the sum is performed only for \( d_{kc} \neq 0 \). In Eqs. (98-99) the index \( G \) runs over the \( N_{\text{aux}} \) auxiliary vectors generated by the Cholesky decomposition. These auxiliary vectors span a basis set that “removes” a possible linear dependence in the two-electron integrals \( K \) and \( \tilde{K} \). Since this is equivalent to removing the contribution of the 0 eigenvalues from the matrix \( \Pi_0 MM^T \), we can assume that \( N_{\text{eig}} = N_{\text{aux}} \). In compact matrix notation we can write Eq. (99) as

\[
\text{tr}\left\{ M^T g(\Pi_0 MM^T) B \right\} = \text{tr}\left\{ M^T \tilde{Q} g(\tilde{D}) \tilde{Q}^{-1} B \right\}, \tag{99}
\]
where we have defined the \((N_{\text{exc}} \times N_{\text{aux}})\) rectangular matrix \(\bar{Q}\), the \((N_{\text{aux}} \times N_{\text{exc}})\) rectangular matrix \(\bar{Q}^{-}\), and the \(N_{\text{aux}} \times N_{\text{aux}}\) diagonal matrix \(\bar{D}\) that contains the non-zero eigenvalues of the non-Hermitian matrix \(\Pi_0 \mathbf{M} \mathbf{M}^T\). The matrix \(\bar{Q}^{-}\) \((\bar{Q}^{-})\) contains the right (left) eigenvectors of \(\Pi_0 \mathbf{M} \mathbf{M}^T\) corresponding to non-zero eigenvalues. One should note that by definition \(\bar{Q}^{-} \bar{Q}^{-} = 1\) (the \((N_{\text{aux}} \times N_{\text{aux}})\) identity matrix) while \(\bar{Q} \bar{Q}^{-} \neq 1\) (the \((N_{\text{exc}} \times N_{\text{exc}})\) identity matrix).

The eigenvalue problem corresponding to the non-zero eigenvalues of the \(\Pi_0 \mathbf{M} \mathbf{M}^T\) can be written in matrix form as

\[
\left(\Pi_0 \mathbf{M} \mathbf{M}^T\right) \bar{Q} = \bar{Q} \bar{D}.
\] (100)

which we can multiply by \(\mathbf{M}^T\) to obtain:

\[
\left(\mathbf{M}^T \Pi_0 \mathbf{M}\right) \mathbf{M}^T \bar{Q} = \mathbf{M}^T \bar{Q} \bar{D},
\] (101)

and to find that the columns of the \((N_{\text{aux}} \times N_{\text{aux}})\) nonsingular square matrix \(\mathbf{M}^T \bar{Q}\) are the eigenvectors of the Hermitian matrix \(\mathbf{M}^T \Pi_0 \mathbf{M}\). The comparison of Eq. (102) and Eq. (101) implies that the non-zero eigenvalues of the matrices \(\Pi_0 \mathbf{M} \mathbf{M}^T\) and \(\mathbf{M}^T \Pi_0 \mathbf{M}\) are identical. Eq. (102) can be used to define the function \(g\) on the matrix \(\mathbf{M}^T \Pi_0 \mathbf{M}\):

\[
g(\mathbf{M}^T \Pi_0 \mathbf{M}) = (\mathbf{M}^T \bar{Q}) g(\bar{D}) (\mathbf{M}^T \bar{Q})^{-1}.
\] (102)

Hence, we have:
\[ g(M^T \Pi_0 M) M^T B = M^T \bar{Q} g(\bar{D}) (M^T \bar{Q})^{-1} M^T B \]
\[ = M^T \bar{Q} g(\bar{D}) \bar{Q}^T B, \quad (103) \]

where in the last step we assumed that

\[ (M^T \bar{Q})^{-1} M^T = \bar{Q}^T. \quad (104) \]

This identity can be inferred from the fact that by definition the rows of the matrix \( \bar{Q}^T \) contain the left eigenvectors of the non-Hermitian matrix \( \Pi_0 M M^T \) corresponding to non-zero eigenvalues:

\[ \bar{Q}^T \Pi_0 M M^T = \bar{D} \bar{Q}^T, \quad (105) \]

and so do the rows of the matrix \( (M^T \bar{Q})^{-1} M^T \) since

\[ (M^T \bar{Q})^{-1} M^T \Pi_0 M M^T \\
= (M^T \bar{Q})^{-1} M^T \Pi_0 M (M^T \bar{Q}) (M^T \bar{Q})^{-1} M^T \\
= \bar{D} (M^T \bar{Q})^{-1} M^T, \quad (106) \]

where the result in Eq. (102) has been used.

By using the results in Eq. (100) and in Eq. (104) we have
\[
\text{tr} \left\{ M^T g(\Pi_0 M M^T) B \right\} = \text{tr} \left\{ M^T \tilde{Q} g(\tilde{D}) \tilde{Q}^{-1} B \right\} = \text{tr} \left\{ g(M^T \Pi_0 M) M B \right\}, \quad (107)
\]

that demonstrates the identity in Eq. (89).

References

New RPA approximations that include exchange effects are derived in the dielectric matrix formalism.

Among these new RPA expressions, the "RPA-a" is the most promising.
